

一、thrift简介

thrift是Facebook开源的一套rpc框架，目前被许多公司使用
我理解的特点

1. 使用IDL语言生成多语言的实现代码，程序员只需要实现自己的业务逻辑
2. 支持序列化和反序列化操作，底层封装协议，传输模块
3. 以同步rpc调用为主，使用libevent evhttp支持http形式的异步调用
4. rpc服务端线程安全，客户端大多数非线程安全
5. 相比protocol buffer效率差些，protocol buffer不支持rpc，需要自己实现rpc扩展，目前有grpc可以使用

由于thrift支持序列化和反序列化，并且支持rpc调用，其代码风格较好并且使用方便，对效率要求不算太高的业务，以及需要rpc的场景，可以选择thrift作为基础库

层次图：

二、编译(thrift for c++ && centos7)

1、官网获取源码包 thrift-0.11.0.tar.gz 解压

```
tar zxvf thrift-0.11.0.tar.gz
```

2、安装依赖

```
yum -y install automake libtool flex bison pkgconfig gcc-c++ boost-devel  
libevent-devel zlib-devel python-devel ruby-devel openssl-devel
```

3、编译boost

使用boost_1_63_0.tar.gz

```
./bootstrap.sh  
./b2
```

4、编译thrift

源码根目录运行

```
./configure && make  
sudo make install
```

5、验证安装

```
thrift -version  
显示 Thrift version 0.11.0
```

三、编写使用IDL编写.thrift文件

这里给出一个thrift的IDL基本语法列表，详细用法可以去官网查找

```
namespace cpp thrift.Test  
//typedef 用法  
typedef i32 MyInt32;  
typedef string MyString;  
typedef i32 UserId;  
//struct 结构定义  
struct TypedefTestStruct  
{  
    1: MyInt32 field_MyInt32;  
    2: MyString field_MyString;  
    3: i32 field_Int32;  
    4: string filed_string;  
}  
//enum 枚举定义  
enum Numberz  
{  
    ONE = 1,  
    TWO,  
    THREE,  
    FIVE = 5,
```

```
SIX,
EIGHT = 8
}
//const 用法
const Numberz myNumberz = Numberz.ONE;
struct Bonk
{
    1: string message,
    2: i32 type
}
//类型嵌套
struct Xtruct
{
    1: string string_thing,
    2: i8 byte_thing,
    3: i32 i32_thing,
    4: i64 i64_thing
}
struct Xtruct2
{
    1: i8 byte_thing,
    2: Xtruct struct_thing,
    3: i32 i32_thing
}
//支持map list set类型分别对应C++中的 map = stl::map list = stl::vector set =
//stl::set
typedef map<string, Bonk> MapType
struct Insanity
{
    1: map<Numberz, UserId> userMap;
    2: list<Xtruct> xtructs;
}
struct CrazyNesting
{
    1: string string_field,
    2: optional set<Insanity> set_field;
    3: required list<map<set<i32>, map<i32, set<list<map<Insanity, string>>>>>> list_field,
    4: binary binary_field
}
//union用法
union SomeUnion
{
    1: map<NumberZ, UserId> map_thing,
    2: string string_thing,
    3: i32 i32_thing,
    4: Xtruct3 xtruct_thing,
    5: Insanity insanity_thing
}
//exception 异常
exception Xception
{
```

```

1: i32 errorCode,
2: string message
}
exception Xception2
{
    1: i32 errorCode,
    2: Xstruct struct_thing
}
// empty struct
struct EmptyStruct{}
struct OneField
{
    1: EmptyStruct field;
}
//service 定义的一组rpc服务,一般是抽象出来的接口调用
service ThriftTest
{
    void testVoid(),
    string testString(1: string thing),
    bool testBool(1: bool thing),
    i8 testByte(1: i8 thing),
    i32 testI32(1: i32 thing),
    i64 testI64(1: i64 thing),
    Xstruct testStruct(1: Xstruct thing),
    Xstruct2 testNest(1: Xstruct2 thing),
    map<string, string> testStringMap(1: map<string, string> thing),
    set<i32> testSet(1: set<i32> thing),
    list<i32> testList(1: list<i32> thing),
    Numberz testEnum(1: Numberz thing),
    map<i32, map<i32,i32>> testMapMap(1: i32 hello),
    map<UserId, map<Numberz,Insanity>> testInsanity(1: Insanity argument)
    ,
    Xstruct testMulti(1: i8 arg0, 2: i32 arg1, 3: i64 arg2, 4: map<i16, string> arg3, 5: Numberz arg4, 6: UserId arg5),
    void testException(1: string arg) throws(1: Xception err1),
    Xstruct testMultiException(1: string arg0, 2: string arg1) throws(1: Xception err1, 2: Xception2 err2),
    oneway void testOneway(1:i32 secondsToSleep)
}

```

四、使用thrift文件生成C++代码

1、生成同步调用的C++代码

```
thrift -r --gen cpp xxx.thrift
```

2、生成异步调用的C++代码(同时同步调用的代码也被生成)

```
thrift --gen cpp:cob_style xxx.thrift
```

五、thrift同步调用

1、StressTest.thrift文件

```
namespace cpp test.stress
service Service {
    void echoVoid(),
    i8 echoByte(1: i8 arg),
    i32 echoI32(1: i32 arg),
    i64 echoI64(1: i64 arg),
    string echoString(1: string arg),
    list<i8> echoList(1: list<i8> arg),
    set<i8> echoSet(1: set<i8> arg),
    map<i8, i8> echoMap(1: map<i8, i8> arg),
}
```

2、使用thrift -r -gen cpp StressTest.thrift 生成代码 gen-cpp目录有

```
StressTest_types.h StressTest_types.cpp StressTest_constants.h StressTest
_constants.cpp Service.h Service.cpp Service_server.skeleton.cpp
```

生成

StressTest_types.h StressTest_constants.h 为相关类型定义文件
Service_server.skeleton为服务端需要的实现文件

3、代码实现

服务端:

```
#include <thrift/concurrency/ThreadManager.h>
#include <thrift/concurrency/PlatformThreadFactory.h>
#include <thrift/concurrency/Thread.h>
#include <thrift/protocol/TBinaryProtocol.h>
#include <thrift/server/TSimpleServer.h>
#include <thrift/server/TNonblockingServer.h>
#include <thrift/transport/TServerSocket.h>
#include <thrift/transport/TNonblockingServerTransport.h>
#include <thrift/transport/TNonblockingServerTransport.h>
#include <thrift/transport/TBufferTransports.h>
#include "Service.h"
using namespace ::apache::thrift;
using namespace ::apache::thrift::protocol;
using namespace ::apache::thrift::transport;
```

```
using namespace ::apache::thrift::server;
using namespace ::test::stress;
class ServiceHandler : virtual public ServiceIf {
public:
    ServiceHandler() {
    }
    void echoVoid() {
        // Your implementation goes here
        printf("echoVoid\n");
    }
    int8_t echoByte(const int8_t arg) {
        printf("echoByte %c\n", arg);
        return arg;
    }
    int32_t echoI32(const int32_t arg) {
        printf("echoI32\n");
        return arg;
    }
    int64_t echoI64(const int64_t arg) {
        printf("echoI64\n");
        return arg;
    }
    void echoString(std::string& _return, const std::string& arg) {
        printf("echoString\n");
    }
    void echoList(std::vector<int8_t> & _return, const std::vector<int8_t>
& arg) {
        printf("echoList\n");
    }
    void echoSet(std::set<int8_t> & _return, const std::set<int8_t> & arg)
{
        printf("echoSet\n");
    }
    void echoMap(std::map<int8_t, int8_t> & _return, const std::map<int8_t,
int8_t> & arg) {
        printf("echoMap\n");
    }
};

int main(int argc, char **argv) {
    int port = 9090;
    stdcxx::shared_ptr<ServiceHandler> handler(new ServiceHandler());
    stdcxx::shared_ptr<TProcessor> processor(new ServiceProcessor(handler));
    stdcxx::shared_ptr<TProtocolFactory> protocolFactory(new TBinaryProtocolFactory());
    stdcxx::shared_ptr<TNonblockingServerTransport> serverTransport(new TNonblockingServerSocket(port));
    stdcxx::shared_ptr<PlatformThreadFactory> threadFactory = std::shared_ptr<PlatformThreadFactory>(new PlatformThreadFactory());
    stdcxx::shared_ptr<ThreadManager> threadManager = ThreadManager::newSimpleThreadManager(10);
```

```

    threadManager->threadFactory(threadFactory);
    threadManager->start();

    stdcxx::shared_ptr<TNonblockingServer> server(new TNonblockingServer(pr
ocessor, protocolFactory, serverTransport, threadManager));

    server->serve();

    return 0;
}

```

我们需要实现ServiceHandler继承Servicelf的相关接口，ServiceHandler是负责相关rpc调用业务的功能实现，

thrift服务器模型基本模型有四种、 SimpleServer ThreadedServer ThreadPoolServer
NoBlockingServer

SimpleServer 简单的单线程模型

ThreadedServer 一个线程一个连接

ThreadPoolServer 线程池

NoBlockingServer 基于libevent的IO复用模型 libevent在linux平台是基于epoll的reactor模型

还有一个异步Server模型TEvhttpServer 基于libevent的evhttp

这里服务端使用了非阻塞epoll实现的thrift服务端模型

客户端:

```

#include <iostream>
#include <string>
#include <thrift/transport/TTransportUtils.h>
#include <thrift/transport/TSocket.h>
#include <thrift/protocol/TBinaryProtocol.h>
#include "Service.h"

using namespace ::test::stress;
using namespace apache::thrift;
using namespace apache::thrift::protocol;
using namespace apache::thrift::transport;

int main()
{
    ::apache::thrift::stdcxx::shared_ptr<TSocket> socket(new TSocket("loc
alhost", 9090));
    ::apache::thrift::stdcxx::shared_ptr<TTransport> transport(new TFrame
dTransport(socket));
    ::apache::thrift::stdcxx::shared_ptr<TProtocol> protocol(new TBinaryP
rotocol(transport));
    ServiceClient client(protocol);
    transport->open();
    std::cout << "client echoByte byte=" << client.echoByte('A') << std::
endl;
    std::cout << "send_echoByte('B')" << std::endl;
}

```

```

        client.send_echoByte('B');
        std::cout << "send_echoByte('C')" << std::endl;
        client.send_echoByte('C');
        std::cout << "recv_echoByte()" << client.recv_echoByte() << std::endl
    ;
    std::cout << "recv_echoByte()" << client.recv_echoByte() << std::endl
    ;
    transport->close();
    return 0;
}

```

客户端使用则比较简单，Service.h定义了相关接口，ServiceClient则是rpc客户类
TTransport new TFrameTransport(socket) 这里创建基于socket的传输层
TProtocol 协议层，序列化后的数据存储方式，这里以TBinaryProtocol 二进制存储

六、thrift异步调用

- 1、thrift文件同同步调用一致
- 2、使用thrift –gen cpp:cob_style StressTest.thrift 生成代码

```

StressTest_types.h StressTest_types.cpp StressTest_constants.h StressTest
_constants.cpp Service.h Service.cpp Service_server.skeleton.cpp Service_
async_server.skeleton.cpp

```

Service_server.skeleton.cpp 同步代码用不到
Service_async_server.skeleton.cpp则为http的异步实现
服务端：

```

#include <thrift/protocol/TBinaryProtocol.h>
#include <thrift/async/TAsyncProtocolProcessor.h>
#include <thrift/async/TEvhttpServer.h>
#include <event.h>
#include <evhttp.h>
#include <iostream>
#include "Service.h"

using namespace ::apache::thrift;
using namespace ::apache::thrift::protocol;
using namespace ::apache::thrift::transport;
using namespace ::apache::thrift::async;

using namespace ::test::stress;

class ServiceHandler : virtual public ServiceIf {
public:
    ServiceHandler() {
    }

```

```

void echoVoid() {
    printf("echoVoid\n");
}

int8_t echoByte(const int8_t arg) {
    printf("echoByte %c\n", arg);
    return arg;
}

int32_t echoI32(const int32_t arg) {
    printf("echoI32\n");
    return arg;
}

int64_t echoI64(const int64_t arg) {
    printf("echoI64\n");
    return arg;
}

void echoString(std::string& _return, const std::string& arg) {
    printf("echoString %s\n", arg.c_str());
    _return = arg;
}

void echoList(std::vector<int8_t> & _return, const std::vector<int8_t> & arg) {
    printf("echoList\n");
}

void echoSet(std::set<int8_t> & _return, const std::set<int8_t> & arg) {
    printf("echoSet\n");
}

void echoMap(std::map<int8_t, int8_t> & _return, const std::map<int8_t, int8_t> & arg) {
    printf("echoMap\n");
}

};

class ServiceAsyncHandler : public ServiceCobSvIf {
public:
    ServiceAsyncHandler() {
        syncHandler_ = std::auto_ptr<ServiceHandler>(new ServiceHandler);
        // Your initialization goes here
    }
    virtual ~ServiceAsyncHandler(){}
};

void echoVoid(::apache::thrift::stdcxx::function<void()> cob) {
    syncHandler_->echoVoid();
}

```

```
    return cob();
}

void echoByte(::apache::thrift::stdcxx::function<void(int8_t const& _return)> cob, const int8_t arg) {
    int8_t _return = 0;
    _return = syncHandler_->echoByte(arg);
    return cob(_return);
}

void echoI32(::apache::thrift::stdcxx::function<void(int32_t const& _return)> cob, const int32_t arg) {
    int32_t _return = 0;
    _return = syncHandler_->echoI32(arg);
    return cob(_return);
}

void echoI64(::apache::thrift::stdcxx::function<void(int64_t const& _return)> cob, const int64_t arg) {
    int64_t _return = 0;
    _return = syncHandler_->echoI64(arg);
    return cob(_return);
}

void echoString(::apache::thrift::stdcxx::function<void(std::string const& _return)> cob, const std::string& arg) {
    std::string _return;
    syncHandler_->echoString(_return, arg);
    return cob(_return);
}

void echoList(::apache::thrift::stdcxx::function<void(std::vector<int8_t> const& _return)> cob, const std::vector<int8_t> & arg) {
    std::vector<int8_t> _return;
    syncHandler_->echoList(_return, arg);
    return cob(_return);
}

void echoSet(::apache::thrift::stdcxx::function<void(std::set<int8_t> const& _return)> cob, const std::set<int8_t> & arg) {
    std::set<int8_t> _return;
    syncHandler_->echoSet(_return, arg);
    return cob(_return);
}

void echoMap(::apache::thrift::stdcxx::function<void(std::map<int8_t, int8_t> const& _return)> cob, const std::map<int8_t, int8_t> & arg) {
    std::map<int8_t, int8_t> _return;
    syncHandler_->echoMap(_return, arg);
    return cob(_return);
}
```

```

protected:
    std::auto_ptr<ServiceHandler> syncHandler_;
};

int main()
{
    ::apache::thrift::stdcxx::shared_ptr<ServiceAsyncProcessor> asynProcessor(new ServiceAsyncProcessor(
        ::apache::thrift::stdcxx::shared_ptr<ServiceCobSvIf>(new ServiceAsyncHandler())));

    ::apache::thrift::stdcxx::shared_ptr<TAsyncProtocolProcessor> asynProtocolProcessor(new TAsyncProtocolProcessor(asynProcessor,
        ::apache::thrift::stdcxx::shared_ptr<TProtocolFactory>(new TBinaryProtocolFactory())));

    TEvhttpServer server(asynProtocolProcessor, 9999);
    server.serve();

    return 0;
}

```

这里实现ServiceHandler的相关业务接口即可实现rpc服务端的相关功能

客户端：

```

#include "Service.h"
#include <string>
#include <iostream>
#include <unistd.h>
#include <thrift/concurrency/ThreadManager.h>
#include <thrift/concurrency/PlatformThreadFactory.h>
#include <thrift/concurrency/Thread.h>
#include <thrift/async/TAsyncChannel.h>
#include <thrift/async/TEvhttpClientChannel.h>
#include <thrift/transport/TSocket.h>
#include <thrift/transport/TTransportUtils.h>
#include <thrift/transport/TBufferTransports.h>
#include <thrift/protocol/TBinaryProtocol.h>
#include <thrift/protocol/TProtocol.h>
#include <event.h>

using namespace ::apache::thrift;
using namespace ::apache::thrift::transport;
using namespace ::apache::thrift::protocol;
using namespace ::apache::thrift::async;
using namespace ::apache::thrift::concurrency;
using namespace ::test::stress;

class MyClient : public ServiceCobClient
{

```

```
public:
    MyClient(stdcxx::shared_ptr<TAsyncChannel> channel, TProtocolFactory*
protocolFactory)
        : ServiceCobClient(channel, protocolFactory)
    {

}
virtual ~MyClient() {}

virtual void completed__(bool success)
{
    if (success)
    {
        std::cout << "completed" << std::endl;
    }
    else
    {
        std::cout << "completed failed" << std::endl;
    }
}

void my_send_byte()
{
    std::cout << "begin my_send_byte" << std::endl;
    stdcxx::function<void(ServiceCobClient*)> cob = stdcxx::bind(&MyClient::recv_byte_callback, this, stdcxx::placeholders::_1);
    echoByte(cob, 'A');
    std::cout << "end my_send_byte" << std::endl;
}

void my_send_string()
{
    std::cout << "begin my_send_string" << std::endl;
    stdcxx::function<void(ServiceCobClient*)> cob = stdcxx::bind(&MyClient::recv_string_callback, this, stdcxx::placeholders::_1);
    echoString(cob, "test asynclient");
    std::cout << "end my_send_string" << std::endl;
}

void recv_byte_callback(ServiceCobClient* client)
{
    std::cout << "recv_byte_callback" << std::endl;
    _res_byte = recv_echoByte();
    std::cout << "_res_byte =" << _res_byte << std::endl;
}

void recv_string_callback(ServiceCobClient* client)
{
    std::cout << "recv_string_callback" << std::endl;
    recv_echoString(_res_string);
    std::cout << "_res_string=" << _res_string << std::endl;
}
```

```

private:
    char _res_byte;
    std::string _res_string;
};

class ClientThread : public Runnable
{
public:
    ClientThread(event_base* base, std::string & host, int port)
        : _base(base), _host(host), _port(port)
    {
    }
    ~ClientThread(){}
    virtual void run()
    {
        stdcxx::shared_ptr<TAsyncChannel> channel1(new TEvhttpClientChannel(_host, "/", _host.c_str(), _port, _base));
        stdcxx::shared_ptr<TAsyncChannel> channel2(new TEvhttpClientChannel(_host, "/", _host.c_str(), _port, _base));

        MyClient client1(channel1, new TBinaryProtocolFactory());
        MyClient client2(channel2, new TBinaryProtocolFactory());

        client1.my_send_byte();
        client1.my_send_string();

        client2.my_send_byte();
        client2.my_send_string();

        while (1)
        {
            client1.my_send_byte();
            sleep(1);
        }
    }
protected:
private:
    event_base* _base;
    std::string _host;
    int _port;
};

int main()
{
    std::string host = "192.168.119.129";
    int port = 9999;

    event_base* base = event_base_new();

    stdcxx::shared_ptr<PlatformThreadFactory> threadFactory = std::shared_ptr<PlatformThreadFactory>(new PlatformThreadFactory());

```

```
    stdcxx::shared_ptr<ThreadManager> threadManager = ThreadManager::newSimpleThreadManager(10);

    threadManager->threadFactory(threadFactory);
    threadManager->start();

    stdcxx::shared_ptr<Thread> thread = threadFactory->newThread(std::shared_ptr<ClientThread>(new ClientThread(base, host, port)));
    thread->start();

    event_base_dispatch(base);
    event_base_free(base);

    return 0;
}
```

客户端则实现了MyClient， MyClient继承公共的rpc服务接口，提供了异步回调的recv_byte_callback, recv_string_callback函数， ClientThread的线程函数的实现则对MyClient异步客户端进了测试

七、简单总结

通过这两天的学习，简单总结一下这个库

- 1、thrift的代码C++代码实现很漂亮，很规范，适合学习阅读
- 2、thrift可以满足很多基本的rpc调用场景
- 3、本文只是简单写了thrift的用法，想深入了解这个库的，其内部实现还是需要化时间好好研究
